Microsoft Access

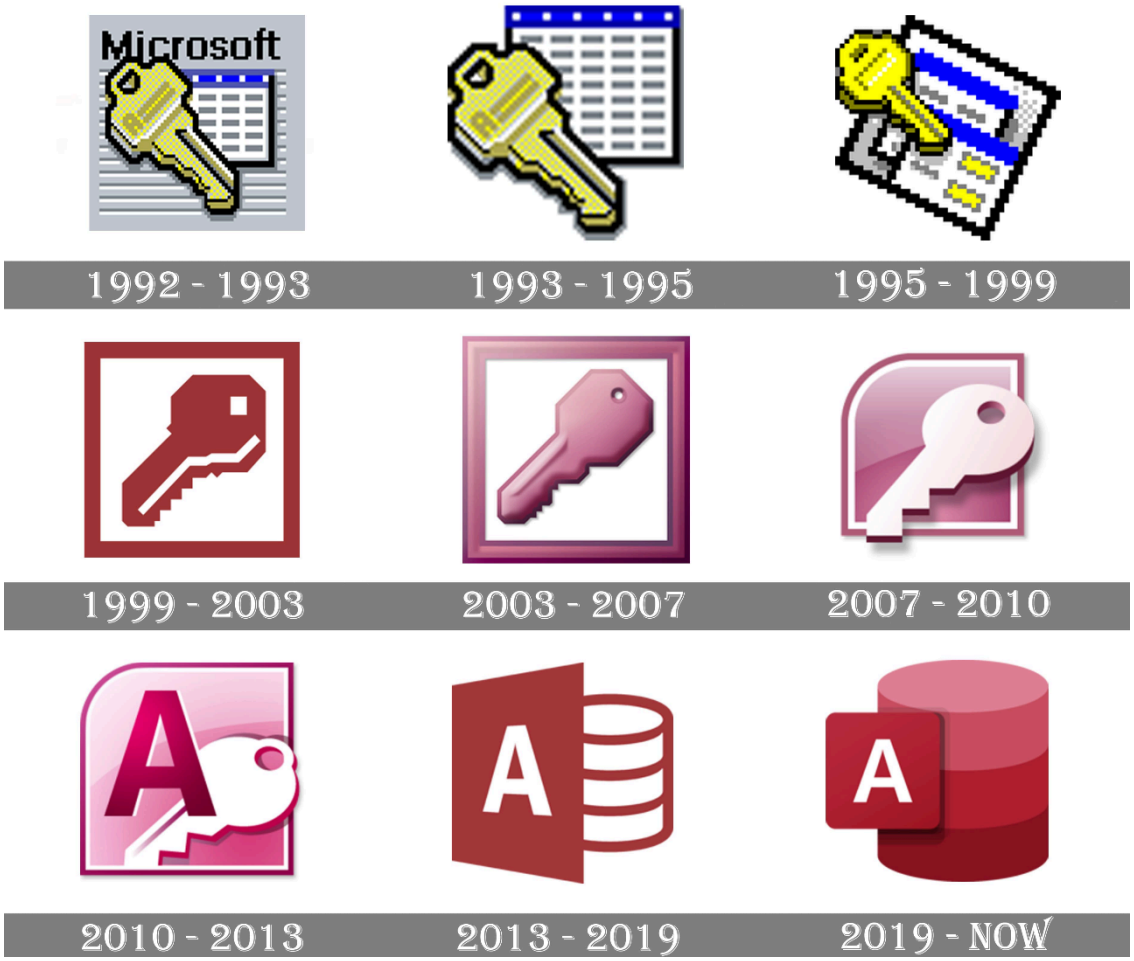

I. Introduction to Microsoft Access

1. Purpose of using Access

Creating a database takes a lot of our time and attention. We need to differentiate between data and storing data. It's important that we gather enough data and process sufficient information to create a database. And we must categorize, arrange and classify that information in tables.

There are many essential benefits and reasons of using Access÷

- Microsoft Access is a sophisticated program, a major step from Excel
- There are numerous careers that require and benefit from this program
- It is crucial in the networking world that transfers data from anywhere in the world
- It is relatively easy to learn, designed with user-friendly interface
- Can remote access, access from smartphone
- It can store virtually unlimited amount of data

Microsoft Access

For your first database, you need a table. Table is where you input data, information and value to create a list of data, table of data. For Access, the columns are called “Field” and the rows are called “Records”. You can create each field and record one at a time. Whenever you add a new field, you have to choose a data field. When you first open Access, you will be welcomed with a table datasheet view. You can fill in data right away. Remember to save regularly and periodically.

Key Components of a Access Table

- Fields: These are the individual pieces of information stored in the table. Each field has a name and a specific data type, which defines what kind of data it can hold, such as text, numbers, dates, or currency.
- Records: Each record corresponds to a single entry in the table, containing values for each field. For example, one record in a product table might have values for Product ID, Product Name, Price, and Stock Quantity.
- Primary Key: This is a unique identifier for each record in a table, ensuring that no two records can have the same key value. In a customer table, the Customer ID might serve as the primary key, allowing easy identification and retrieval of customer information.

1. Table

To create a new table, you may want to create a table on Design view. To do that, go to:

- Create Tab, select Table design
- Write the name of your field on Field Name
- Choose the data type for each field

Now you can go to Datasheet view to fill in data and values. For Description cell on Design View, it’s just optional detail if you want to apply a notice on a field.

Lookup Wizard is a Data type for creating a list of choice values or data. You can create it in 2 ways; create using an existing table and create a new set of value lists. You can simply create a lookup wizard by just write the value you want by:

- Choosing Lookup Wizard data type
- Choose to type your own value
- Write down of value in Col1 field then click Next
- Label it with a name then click Finish
